About

a python package to process protein cross-linking data

pyXLMS is a python package and web application with graphical user interface that aims to simplify and streamline the intermediate step of connecting crosslink search engine results with down-stream analysis tools, enabling researchers even without bioinformatics knowledge to conduct in-depth crosslink analyses and shifting the focus from data transformation to data interpretation and therefore gaining biological insight.

Currently pyXLMS supports input from seven different crosslink search engines: [MaxLynx](#) (part of [MaxQuant](#)), [MeroX](#), [MS Annika](#), [pLink 2](#) and [pLink 3](#), [Scout](#), [xiSearch](#) and [xiFDR](#), [XlinkX](#), as well as the [mzIdentML format](#) of the HUPO Proteomics Standards Initiative, and a well-documented and [human-readable custom tabular format](#).
